

Step 1.6 - Acceptance Criteria Definition Implementation Report

Objective

- Define canonical, testable acceptance criteria for all approved user stories in CareFlow Health.

Architecture and context

- Frontend-only healthcare simulation; no backend, APIs, API automation, or real PHI.
- Acceptance criteria layer sits between user stories and test scenario/test case layers.

What was implemented

- Created CFH-AC-001 acceptance criteria document.
- Added criteria for all 32 user stories with stable IDs and BDD representation.
- Added cross-cutting NFR acceptance criteria and updated traceability.

Acceptance criteria approach

- Three core criteria per story: happy path, validation/negative behavior, and state/accessibility/responsive behavior.
- Per-story automation/testability notes added for future execution stability.

Example acceptance criteria

- AC-US-001-001-001 Happy Path
- AC-US-004-003-002 Validation/Negative flow
- AC-NFR-003 Accessibility cross-cutting criterion

BDD examples

- Given the user has required role access
- When the user performs the workflow action
- Then expected outcome is visible and traceable

Traceability approach

- Maintained BRD -> PRD -> Epic -> User Story -> Acceptance Criteria chain.
- Updated requirements-traceability with story-to-AC mapping and coverage summary.

QA automation relevance

- Criteria are automation-ready for future Playwright + TypeScript + Cucumber + POM implementation.
- No automation code was implemented in this step.

RAG, MCP, LangGraph relevance

- Stable IDs and atomic criteria improve retrieval and AI reasoning quality.
- MCP/Agent operations are prepared conceptually, not implemented.

Validation results

- User Stories covered: 32/32
- Story-mapped AC count: 96
- Cross-cutting NFR AC count: 13
- Total AC count: 109
- User stories without AC: 0
- Orphan AC: 0
- Unmapped AC: 0

Interview questions and answers

- How AC differs from requirements and test cases.
- How BDD formatting improves downstream implementation speed.
- How traceability reduces coverage risk.

Lessons learned

- Cross-cutting NFRs should be documented globally while keeping story AC focused on business behavior.
- Stable identifier design significantly reduces downstream ambiguity.

Future implementation steps

- Step 1.7 Test Scenario Definition (not executed automatically).
